Structure of Lectures

- Pessimistic lower bound for non convex problems
 - Resisting oracle
- Optimal estimation for convex optimization problems
 - Lower complexity bounds
 - Optimal and not optimal methods
 - Mirror Descent
 - Gradient Descent
- Similar Triangles Method (Fast Gradient Method)
 - Open gap problem of A. Nemirovski
- Structural optimization (looking into the Black Box)
 - Conditional problems
 - Interior Point Method

Two practice examples (A. Nemirovski)

Stability number of graph

$$\sum_{i=1}^n x_i \rightarrow \max_{\substack{x_i^2 - x_i = 0 \\ x_i x_j = 0, (i, j) \in \Gamma}} , n = 256.$$

La Tour Eiffel problem

$$x_0 \rightarrow \min_{\substack{\lambda_{\min} \begin{pmatrix} x_1, \dots, x_1 \\ \dots \\ \dots \\ \dots x_m, x_m \\ x_1^l, \dots, x_m^l, x_0 \end{pmatrix} \geq 0, l=1, \dots, k \\ \sum_{j=1}^m a_j x_j^l = b^l, l=1, \dots, k; \sum_{j=1}^m x_j = 1,}} , k = 6, m = 160.$$

Which of these two problems harder to solve? Intuition says – the second. But the first problem is not convex and it's NP-hard. The best known method finds 0.5-solution required $2^n \approx 10^{77}$ flop. The second problem is convex and one can find 10^{-6} -solution by CVX for few seconds.

Pessimistic lower bound for non convex problems

Assume that we have to solve $(B_\infty^n(1) - \text{unit cube in } \mathbb{R}^n)$

$$F(x) \rightarrow \min_{x \in B_\infty^n(1)},$$

in sense

$$F(x^N) - \min_{x \in B_\infty^n(1)} F(x) \leq \varepsilon,$$

where $\left| d^k F(x + te) / dt^k \right| \leq 1$ for all $e \in B_\infty^n(1)$, $1 \leq k \leq n$.

For arbitrary method imposed with local oracle (this oracle in request for fixed point can return as high derivatives of $F(x)$ as we asked) we have that required number of (randomized) oracle calls is: $\boxed{N \succ \varepsilon^{-n/k}}$ and for one extremum problem for deterministic oracle is: $\boxed{N \succ \varepsilon^{-(n-1)/k}}$.

Resisting oracle: Uniform Grid method is worst-case optimal.

Resisting oracle (build online “bad” function for the method)

For simplicity consider 0-order oracle (return the value of the function).

Divide $B_\infty^n(1)$ on m^n sub-cubes $B_\infty^n(1/(2m))$. Assume that

$$|F(y) - F(x)| \leq M \|y - x\|_\infty.$$

At each point reply $F(x^k) = 0$. When $N < m^n$ there is ball $B_\infty^n(1/(2m))$ with no question. Hence we can take

$$\min_{x \in B_\infty^n(1)} F(x) = -\frac{M}{2m}.$$

Thus $\varepsilon \geq M/(2m)$. Therefore, choosing $N = m^n - 1$ one can obtain:

$$\boxed{N \geq \left(\frac{M}{2\varepsilon}\right)^n - 1.}$$

Optimal estimation for Convex Optimization problems ($N \geq n$)

$$F(x) \rightarrow \min_{x \in Q},$$

Q – compact (it's significant!) convex set, $n = \dim x$. We assume that $F(x^N) - F_* \leq \varepsilon$, where N – number of required iterations (calculations $\partial F(x)$ or separation hyperplane to Q or its cutting part).

$$\boxed{N \sim n \ln(\Delta F / \varepsilon)},$$

where $\Delta F = \sup_{x, y \in Q} \{F(y) - F(x)\}$. Additional iteration complexity is $\boxed{\tilde{O}(n^2)}$.

Lee Y.-T., Sidford A., Wong S.C-W. A faster cutting plane methods and its implications for combinatorial and convex optimization // e-print, 2015.

<https://arxiv.org/pdf/1508.04874v2.pdf>

Ellipsoid method: $N \sim n^2 \ln(\varepsilon^{-1})$. Additional iteration complexity is $\tilde{O}(n^2)$.

LP in P by ellipsoid algorithm (L. Khachyan, 1978)

Assume we have to answer is $Ax \leq b$ solvable ($n = \dim x$, $m = \dim b$)? We assume that all elements of A and b are integers. And we'd like to find one of **the exact** solutions x_* . This problem up to a logarithmic factor in complexity is equivalent to find the exact solution of LP problem $\langle c, x \rangle \rightarrow \min_{Ax \leq b}$ with integer A , b and c . To find the exact solution of $Ax = b$ one can use polynomial Gauss algorithm $O(n^3)$. What is about $Ax \leq b$? Let's introduce

$$L = \sum_{i,j=1,1}^{m,n} \log_2 |a_{ij}| + \sum_{i=1}^m \log_2 |b_i| + \log_2(mn) + 1.$$

Useful properties: $\|x_*\|_\infty \leq 2^L$; if $Ax - b \leq 0$ isn't true then $\|(Ax - b)_+\|_\infty \geq 2^{-(L-1)}$.

Works in $O(nL)$ -bit arithmetic with $\tilde{O}(mn + n^2)$ cost of PC memory one can find x_* (if it's exist) for $\tilde{O}(n^3(n^2 + m)L)$ arithmetic operations: $\times, \pm, /, \sqrt{\quad}, \max$.

LP in P? – is still an open question

Simplex Method (Kantorovich–Dantzig) solve (exactly since it’s finite method) LP in polynomial time $\tilde{O}(m^3)$ only “in average” (Borgward, Smale, Vershik–Sporyshev; 1982–1986). Klee–Minty example (1972) shows that in worst case simplex methods required to get round all the vertexes of polyhedral (exponential number). At the very beginning of this century Spielman–Tseng (smooth analysis) show that if $A := A + \|A\|G$, where $G = \left\|g_{ij}\right\|_{i,j=1,1}^{m,n}$, i.i.d. $g_{ij} \in N(0, \tilde{\sigma}^2)$ and $T_{\tilde{\sigma}}(A)$ – time required by special version of Simplex Method to find exact solution, then

$$E_G [T_{\tilde{\sigma}}(A)] = \text{Poly}(n, m, \tilde{\sigma}^{-1}). // \log(\tilde{\sigma}^{-1})? – an open question$$

In ideal arithmetic with real numbers it is still an open question (Blum–Shub–Smale): is it possible to find **the exact** solution of LP problem (with real numbers) in polynomial time in ideal arithmetic ($\pi \cdot e$ – costs $O(1)$).

Optimal estimations for Convex Optimization problems ($N \leq n$)

$$F(x) \rightarrow \min_{x \in Q}.$$

We assume that

$$F(x^N) - F_* \leq \varepsilon.$$

N – number of required iterations (calculations of $F(x)$ and $\partial F(x)$).

R – “distance” between starting point and nearest solution.

N	$ F(y) - F(x) \leq M \ y - x\ $	$\ \nabla F(y) - \nabla F(x)\ _* \leq L \ y - x\ $
$F(x)$ convex	$\frac{M^2 R^2}{\varepsilon^2}$	$\sqrt{\frac{LR^2}{\varepsilon}}$
$F(x)$ μ -strongly convex	$\frac{M^2}{\mu \varepsilon}$	$\sqrt{\frac{L}{\mu}} \left\lceil \ln \left(\frac{\mu R^2}{\varepsilon} \right) \right\rceil (\forall N)$

If norm is non euclidian then the last row is true up to $O(\ln n)$ -factor.

Lower complexity bound. Non smooth case ($N < n$)

Let's introduce

$$Q = B_2^n(2R), F_N(x) = M \max_{1 \leq i \leq N} x_i + \frac{\mu}{2} \|x\|_2^2, \mu = \frac{M}{R\sqrt{N}},$$

$$x^{k+1} = x^0 + \text{Lin} \left\{ \partial f(x^0), \dots, \partial f(x^k) \right\}. // \text{ method}$$

Solving the problem

$$M\tau + \frac{\mu N}{2} \tau^2 \rightarrow \min_{\tau}$$

we get $\tau_* = -R/\sqrt{N}$, $\|x_*\|_2^2 = N\tau_*^2 = R^2$, $F_N^* = \min_{x \in Q} F_N(x) = -MR/\sqrt{N}$. If

$x^0 = 0$ then after N iteration we can keep $x_i^N = 0$ for $i > N$. So we have

$$F_{N+1}(x^{N+1}) - F_{N+1}^* \geq -F_{N+1}^* = \left\{ \frac{MR}{\sqrt{N+1}}, \frac{M^2}{2\mu \cdot (N+1)} \right\}.$$

Lower complexity bound. Smooth case

Let's introduce ($2N + 1 < n$): $x^0 = 0$, $x^k \in \text{Lin} \left\{ \nabla f(x^0), \dots, \nabla f(x^k) \right\}$,

$$F_N(x) = \frac{L}{8} \left[x_1^2 + \sum_{i=1}^{2N+1} (x_i - x_{i+1})^2 + x_{2N+1}^2 \right] - \frac{L}{4} x_1,$$

Then

$$\min_{1 \leq i \leq N} F_N(x^i) - F_N^* \geq \frac{3L}{32} \frac{\|x^1 - x_*\|_2^2}{(N+1)^2}.$$

Let's introduce $\chi = L/\mu$

$$F(x) = \frac{\mu \cdot (\chi - 1)}{8} \left[x_1^2 + \sum_{i=1}^{\infty} (x_i - x_{i+1})^2 - 2x_1 \right] + \frac{\mu}{2} \|x\|_2^2$$

Then

$$F(x^N) - F_* \geq \frac{\mu}{2} \left(\frac{\sqrt{\chi} - 1}{\sqrt{\chi} + 1} \right)^{2(N-1)} \cdot \|x^1 - x_*\|_2^2 \quad (\text{with arbitrary } N \geq 1).$$

Optimal method for non-smooth convex case (B. Polyak, N. Shor)

Let's consider unconstrained convex case

$$f(x) \rightarrow \min_x. \quad (1)$$

We search such \bar{x}^N that

$$f(\bar{x}^N) - f_* \leq \varepsilon,$$

where $f_* = f(x_*)$ – optimal value of function in (1), x_* – solution of (1).

Let's introduce

$$\tilde{B}_2^n(x_*, R) = \{x \in \mathbb{R}^n : \|x - x_*\|_2 \leq R\}.$$

The main iterative process is (for simplicity we'll denote $\partial f(x) = \nabla f(x)$)

$$\boxed{x^{k+1} = x^k - h \nabla f(x^k)}. \quad (2)$$

Assume that under $x \in \tilde{B}_2^n(x_*, \sqrt{2}R)$

$$\|\nabla f(x)\|_2 \leq M,$$

where $R = \|x^0 - x_*\|_2 = \|x_*\|_2$.

Hence from (2), (5) we have

$$\begin{aligned} \|x - x^{k+1}\|_2^2 &= \|x - x^k + h\nabla f(x^k)\|_2^2 = \\ &= \|x - x^k\|_2^2 + 2h\langle \nabla f(x^k), x - x^k \rangle + h^2 \|\nabla f(x^k)\|_2^2 \leq \\ &\leq \|x - x^k\|_2^2 + 2h\langle \nabla f(x^k), x - x^k \rangle + h^2 M^2. \end{aligned} \quad (3)$$

Here we choose $x = x_*$ (if x_* isn't unique, we choose the nearest x_* to x^0)

$$\begin{aligned}
f\left(\frac{1}{N}\sum_{k=0}^{N-1}x^k\right)-f_* &\leq \frac{1}{N}\sum_{k=0}^{N-1}f(x^k)-f(x_*) \leq \frac{1}{N}\sum_{k=0}^{N-1}\langle \nabla f(x^k), x^k-x_* \rangle \leq \\
&\leq \frac{1}{2hN}\sum_{k=0}^{N-1}\left\{\|x_*-x^k\|_2^2-\|x_*-x^{k+1}\|_2^2\right\}+\frac{hM^2}{2}= \\
&= \frac{1}{2hN}\left(\|x_*-x^0\|_2^2-\|x_*-x^N\|_2^2\right)+\frac{hM^2}{2}.
\end{aligned}$$

If

$$h = \frac{R}{M\sqrt{N}}, \quad \bar{x}^N = \frac{1}{N}\sum_{k=0}^{N-1}x^k,$$

then

$$\boxed{f(\bar{x}^N)-f_* \leq \frac{MR}{\sqrt{N}}}. \quad (4)$$

This means that

$$\boxed{N = \frac{M^2 R^2}{\varepsilon^2}}, \quad \boxed{h = \frac{\varepsilon}{M^2}}.$$

Note that

$$0 \leq \frac{1}{2hk} \left(\|x_* - x^0\|_2^2 - \|x_* - x^k\|_2^2 \right) + \frac{hM^2}{2},$$

Hence for all $k = 0, \dots, N$

$$\|x_* - x^k\|_2^2 \leq \|x_* - x^0\|_2^2 + h^2 M^2 k \leq 2 \|x_* - x^0\|_2^2,$$

therefore

$$\boxed{\|x^k - x_*\|_2 \leq \sqrt{2} \|x^0 - x_*\|_2}, \quad k = 0, \dots, N. \quad (5)$$

For general (constrained) case

$$f(x) \rightarrow \min_{x \in Q} \quad (6)$$

we introduce norm $\|\cdot\|$, prox-function $d(x) \geq 0$ ($d(x^0) = 0$) which is 1-strictly convex due to $\|\cdot\|$ and Bregman's divergence

$$V(x, z) = d(x) - d(z) - \langle \nabla d(z), x - z \rangle.$$

We put $R^2 = V(x_*, x^0)$, where x_* – is solution of (6) (if x_* isn't unique then we assume that x_* is minimized $V(x_*, x^0)$). So instead of (3) we'll have

$$2V(x, x^{k+1}) \leq 2V(x, x^k) + 2h \langle \nabla f(x^k), x - x^k \rangle + h^2 M^2 \quad (\|\nabla f(x)\|_* \leq M).$$

Mirror Descent (A. Nemirovski, 1977), for $k = 0, \dots, N - 1$

$$x^{k+1} = \text{Mirr}_{x^k} \left(h \partial f(x^k) \right), \quad \text{Mirr}_{x^k}(v) = \arg \min_{x \in Q} \left\{ \langle v, x - x^k \rangle + V(x, x^k) \right\}.$$

And analogues of formulas (4), (5) are also valid.

$$f(\bar{x}^N) - f_* \leq \frac{\sqrt{2MR}}{\sqrt{N}}, \quad \|x^k - x_*\| \leq 2\sqrt{V(x_*, x^0)}, \quad h = \frac{\varepsilon}{M^2}.$$

Typically, $\frac{1}{2}\|x_* - x^0\|^2 \leq R^2 \leq C \ln n \cdot \|x_* - x^0\|^2$.

Examples

Example 1. $Q = \mathbb{R}_+^n = \{x \in \mathbb{R}^n : x \geq 0\}$, $\|\nabla f(x)\|_2 \leq M$, $x \in Q$,

$$\|\cdot\| = \|\cdot\|_2, \quad d(x) = \frac{1}{2}\|x - \bar{x}\|_2^2, \quad \bar{x} \in \text{int } Q, \quad h = \varepsilon/M^2, \quad x^0 = \bar{x},$$

$$x^{k+1} = \left[x^k - h\nabla f(x^k) \right]_+ = \max \{ x^k - h\nabla f(x^k), 0 \}, \quad k = 1, \dots, N-1,$$

where $\max \{ \cdot \}$ is taken component-wise. \square

Example 2. $Q = S_n(1) = \left\{ x \in \mathbb{R}_+^n : \sum_{k=1}^n x_k = 1 \right\}$, $\|\nabla f(x)\|_\infty \leq M$, $x \in Q$,

$$\|\cdot\| = \|\cdot\|_1, \quad d(x) = \ln n + \sum_{i=1}^n x_i \ln x_i, \quad h = M^{-1} \sqrt{2 \ln n / N}, \quad x_i^0 = 1/n, \quad i = 1, \dots, n,$$

For $k = 0, \dots, N-1$, $i = 1, \dots, n$

$$x_i^{k+1} = \frac{\exp\left(-h \sum_{r=1}^k \nabla_i f(x^r)\right)}{\sum_{l=1}^n \exp\left(-h \sum_{r=1}^k \nabla_l f(x^r)\right)} = \frac{x_i^k \exp\left(-h \nabla_i f(x^k)\right)}{\sum_{l=1}^n x_l^k \exp\left(-h \nabla_l f(x^k)\right)},$$

$$f(\bar{x}^N) - f_* \leq M \sqrt{\frac{2 \ln n}{N}} \quad (\bar{x}^N = \frac{1}{N} \sum_{k=0}^{N-1} x^k). \quad \square$$

Optimal method for non-smooth strongly convex case

Assume that $f(x)$ is additionally μ -strongly convex in $\|\cdot\|_2$ norm:

$$f(y) + \langle \nabla f(y), x - y \rangle + \frac{\mu}{2} \|x - y\|_2^2 \leq f(x) \text{ (for all } x, y \in Q \text{)}.$$

Introduce
$$x^{k+1} = \text{Mirr}_{x^k} \left(h_k \partial f(x^k) \right),$$

$$h_k = \frac{2}{\mu \cdot (k+1)}, \quad d(x) = \frac{1}{2} \|x - x^0\|_2^2, \quad \|\nabla f(x)\|_2 \leq M, \quad x \in Q.$$

Then (Lacoste-Julien–Schmidt–Bach, 2012)

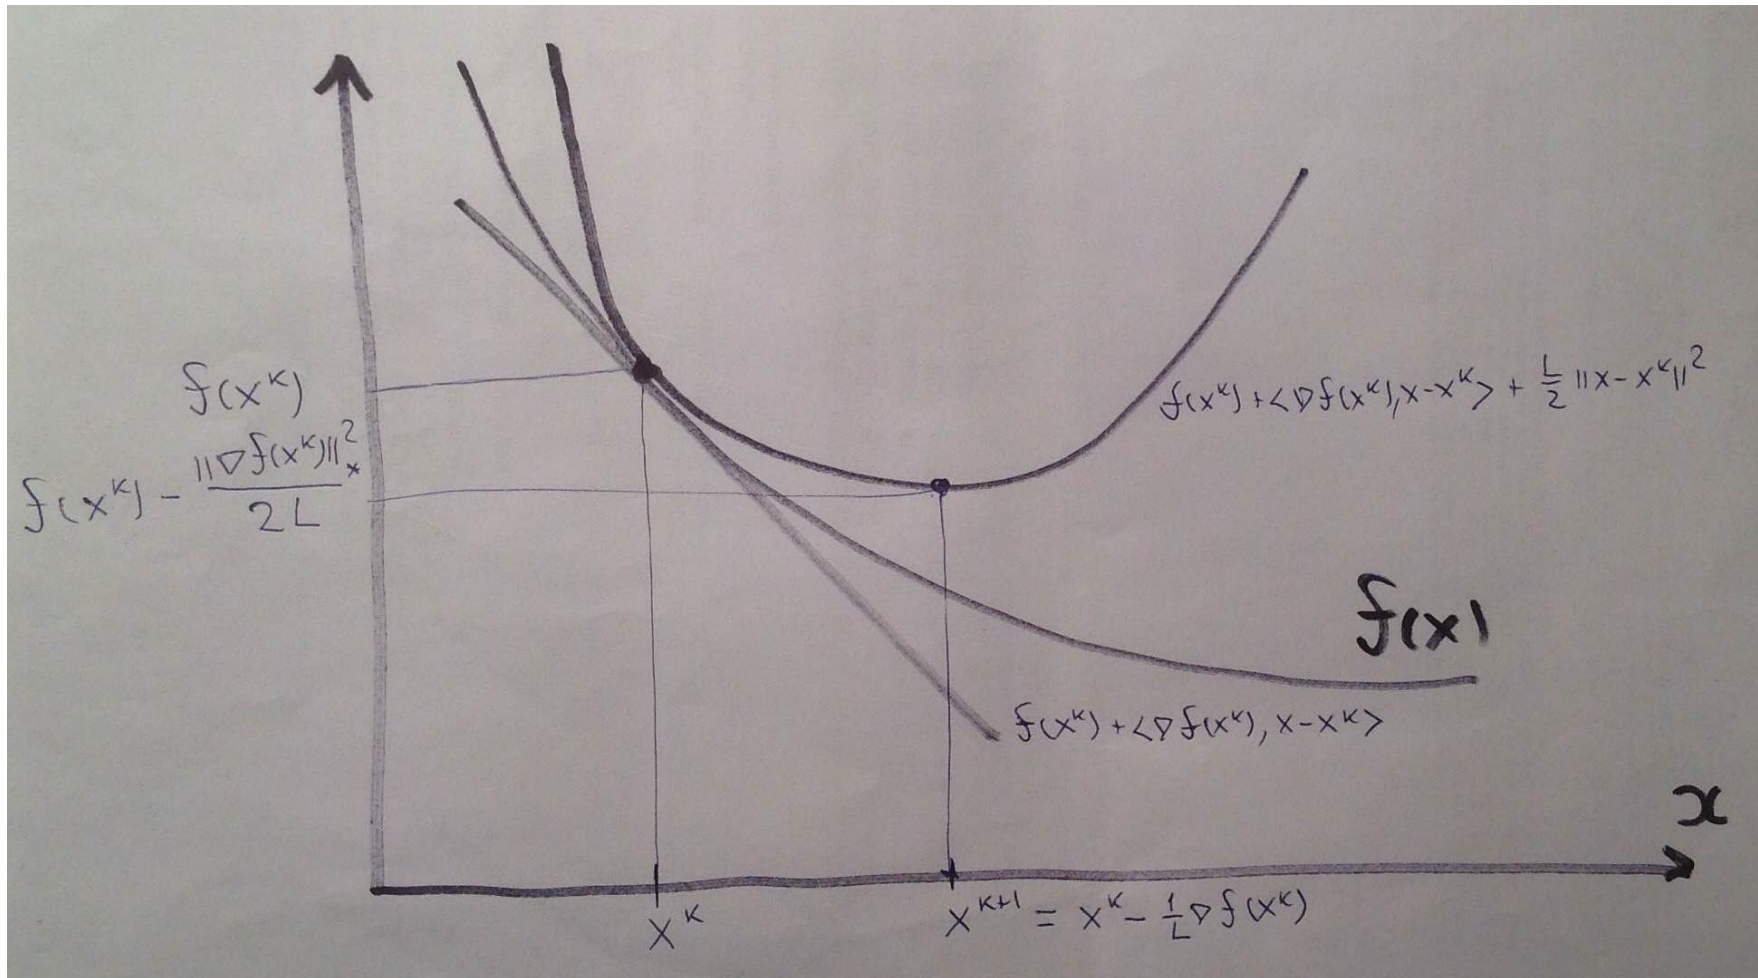

$$\boxed{f \left(\sum_{k=1}^N \frac{2k}{k(k+1)} x^k \right) - f_* \leq \frac{2M^2}{\mu \cdot (k+1)}}.$$

Hence

$$\boxed{N \simeq \frac{2M^2}{\mu \varepsilon}}.$$

Gradient descent is not optimal method for smooth convex case

$$\|\nabla f(y) - \nabla f(x)\|_* \leq L\|y - x\|$$

$$x^{k+1} = \arg \min_{x \in Q} \left\{ f(x^k) + \langle \nabla f(x^k), x - x^k \rangle + \frac{L}{2} \|x - x^k\|^2 \right\},$$

$$f(x^N) - f_* \leq \frac{2L\tilde{R}^2}{N}, \quad \tilde{R}^2 = \max_{x \in Q, f(x) \leq f(x_0)} \|x - x_*\|.$$

In Euclidian case (2-norm) one can simplify

$$x^{k+1} = \pi_Q \left(x^k - \frac{1}{L} \nabla f(x^k) \right),$$

$$f(x^N) - f_* \leq \frac{2LR^2}{N}, \quad R = \|x^0 - x_*\|_2.$$

If $Q = \mathbb{R}^n$ one has

$$x^{k+1} = x^k - \frac{1}{L} \nabla f(x^k).$$

Unfortunately, convergence of simple gradient descent isn't optimal!

Polyak's heavy ball method

Gradient descent (Cauchy, 1847):

$$\frac{dx}{dt} = -\nabla f(x); \quad x^{k+1} = x^k - \frac{1}{L} \nabla f(x^k).$$

Lyapunov's functions: $V(x) = f(x) - f_*$, $V(x) = \|x - x_*\|_2^2$ (convex case).

Heavy ball method (Polyak, 1964):

$$\frac{dx}{dt} = y, \quad \frac{dy}{dt} = -ay - b\nabla f(x); \quad x^{k+1} = x^k - \alpha \nabla f(x^k) + \beta \cdot (x^k - x^{k-1}).$$

Lyapunov's function: $V(x) = f(x) + \frac{1}{2b} \|y\|_2^2$ – full energy (convex case).

Wilson A., Recht B., Jordan M. <https://arxiv.org/pdf/1611.02635v1.pdf>

Local convergence is optimal. Now we describe global optimal method.

Optimal method for smooth convex case

Estimation functions technique (Yu. Nesterov)

$$d(y^0) = 0, d(x) \geq 0, V(x, z) = d(x) - d(z) - \langle \nabla d(z), x - z \rangle,$$

$$\varphi_0(x) = V(x, y^0) + \alpha_0 \left[f(y^0) + \langle \nabla f(y^0), x - y^0 \rangle \right],$$

$$\varphi_{k+1}(x) = \varphi_k(x) + \alpha_{k+1} \left[f(y^{k+1}) + \langle \nabla f(y^{k+1}), x - y^{k+1} \rangle \right]$$

$$x^0 = u^0 = \arg \min_{x \in Q} \varphi_0(x), A_k = \sum_{i=0}^k \alpha_i, \alpha_0 = L^{-1}, A_k = \alpha_k^2 L,$$

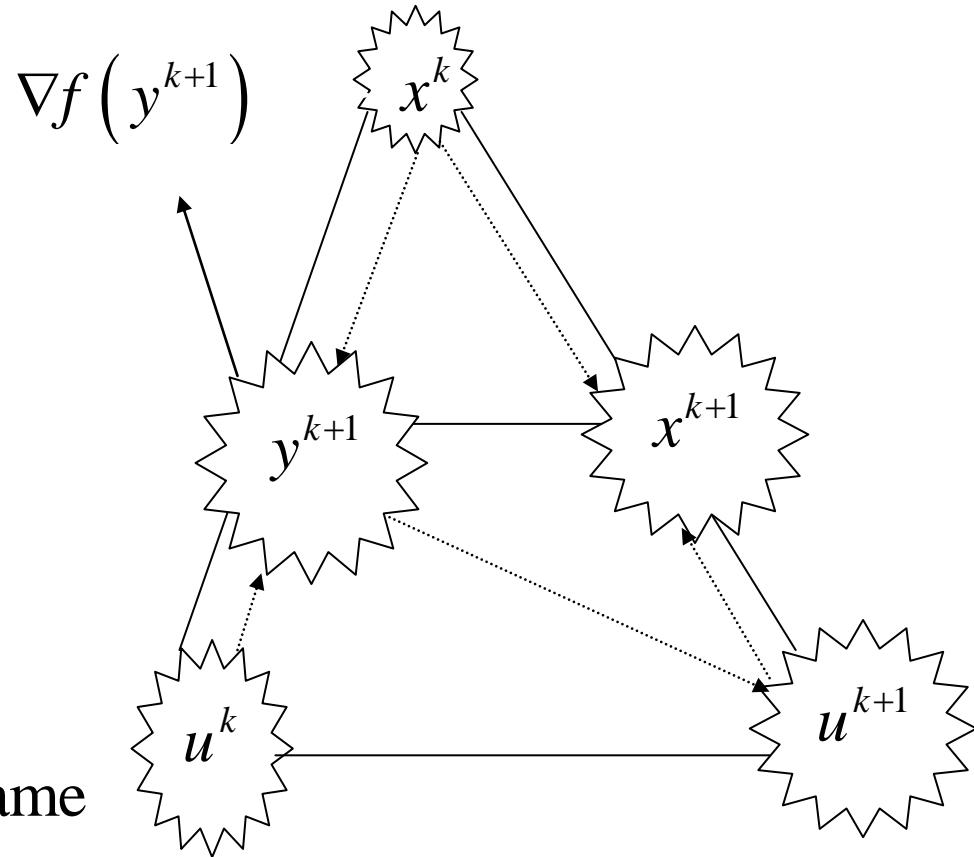

$$\alpha_{k+1} = \frac{1}{2L} + \sqrt{\frac{1}{4L^2} + \alpha_k^2}, A_k \geq \frac{(k+1)^2}{4L}, k = 0, 1, 2, \dots$$

Similar Triangles Method (Yu. Nesterov; 1983, 2016)

$$\begin{aligned}
 y^{k+1} &= \frac{\alpha_{k+1} u^k + A_k x^k}{A_{k+1}}, \\
 u^{k+1} &= \arg \min_{x \in Q} \varphi_{k+1}(x), \\
 x^{k+1} &= \frac{\alpha_{k+1} u^{k+1} + A_k x^k}{A_{k+1}}.
 \end{aligned}$$

$$u^{k+1} = \text{Mirr}_{y^0} \left(\sum_{i=0}^{k+1} \alpha_i \nabla f(y^i) \right) \text{ the same}$$

$$u^{k+1} = \text{Mirr}_{u^k} \left(\alpha_{k+1} \nabla f(y^{k+1}) \right) \text{ mirror version (Alexander Turin, HSE)}$$

Assume that

$$\|\nabla f(y) - \nabla f(x)\|_* \leq L\|y - x\| \text{ (for all } x, y \in Q\text{)}.$$

Then

$$f(x^N) - \min_{x \in Q} f(x) \leq \frac{4LR^2}{(N+1)^2}.$$

That is $N \simeq 2\sqrt{LR^2/\varepsilon}$. And for all $k = 0, 1, 2, \dots$

$$\|u^k - x_*\|^2 \leq 2V(x_*, y^0),$$

$$\max \left\{ \|x^k - x_*\|^2, \|y^k - x_*\|^2 \right\} \leq 4V(x_*, y^0) + 2\|x^0 - y^0\|^2.$$

Optimal method for smooth strongly convex case

$$\varphi_0(x) = V(x, y^0) + \alpha_0 \left[f(y^0) + \langle \nabla f(y^0), x - y^0 \rangle + \frac{\mu}{2} \|x - y^0\|_2^2 \right],$$

$$\varphi_{k+1}(x) = \varphi_k(x) + \alpha_{k+1} \left[f(y^{k+1}) + \langle \nabla f(y^{k+1}), x - y^{k+1} \rangle + \frac{\mu}{2} \|x - y^k\|_2^2 \right],$$

$$A_k = \sum_{i=0}^k \alpha_i, \quad \alpha_0 = L^{-1}, \quad A_{k+1} \cdot (1 + A_k \mu) = \alpha_{k+1}^2 L, \quad x^0 = u^0 = \arg \min_{x \in Q} \varphi_0(x),$$

$$\alpha_{k+1} = \frac{1 + A_k \mu}{2L} + \sqrt{\frac{1 + A_k \mu}{4L^2} + \frac{A_k \cdot (1 + A_k \mu)}{L}}, \quad A_{k+1} = A_k + \alpha_{k+1},$$

$$A_k \geq \frac{1}{L} \left(1 + \frac{1}{2} \sqrt{\frac{\mu}{L}} \right)^{2k} \geq \exp \left(\frac{k}{2} \sqrt{\frac{\mu}{L}} \right), \quad k = 0, 1, 2, \dots$$

Then using Similar Triangles Method with new estimating functions sequence and new step size policy one can obtain (continuous on $\mu \geq 0$)

$$f(x^N) - \min_{x \in Q} f(x) \leq \min \left\{ \frac{4LR^2}{(N+1)^2}, LR^2 \exp\left(-\frac{N}{2} \sqrt{\frac{\mu}{L}}\right) \right\}.$$

In other “words”

$$N \approx 2 \sqrt{\frac{L}{\mu}} \ln \left(\frac{LR^2}{\varepsilon} \right).$$

Unfortunately here and before, in strongly convex case we were significantly restricted by Euclidian norm/prox-structure. Generalization requires another approach: restarts technique.

For $Q = \mathbb{R}^n$ one can simplify method (Yu. Nesterov; 1983, 2001)

$$x^0 = y^0,$$

$$x^{k+1} = y^k - \frac{1}{L} \nabla f(y^k),$$

$$y^{k+1} = x^{k+1} + \frac{\sqrt{L} - \sqrt{\mu}}{\sqrt{L} + \sqrt{\mu}} (x^{k+1} - x^k).$$

Unfortunately, this method isn't continuous on $\mu > 0$.

Note: In smooth case from $f(x^N) - f(x_*) \leq \varepsilon$ one has that

$$\|\nabla f(x^N)\|^2 \leq 2L\varepsilon \quad (\|\nabla f(x_*)\|^2 = 0).$$

and in strongly convex case (geometric convergence in argument)

$$\|x^N - x_*\|_2^2 \leq 2\mu\varepsilon.$$

Open gap problem (A. Nemirovski, 2015)

Assume that $Q = B_1^n(R)$ (ball in \mathbb{R}^n of radius R in 1-norm),

$$\|\nabla f(y) - \nabla f(x)\|_2 \leq L_2 \|y - x\|_2.$$

Then for $N \leq n$ and arbitrary method with local first order oracle

$$f(x^N) - f_* \geq \frac{C_1 L_2 R^2}{N^3}.$$

When $\|\nabla f(y) - \nabla f(x)\|_\infty \leq L_1 \|y - x\|_1$ Similar Triangles Methods takes us

$$f(x^N) - f_* \leq \frac{C_2 L_1 R^2}{N^2},$$

where $L_2/n \leq L_1 \leq L_2$. Unfortunately, we can't say that there is no gap between lower and upper bounds.

Optimality

Meanwhile, for the most interesting convex sets Q there exists such a norm $\|\cdot\|$ and appropriate prox-structure $d(x)$ that Mirror Descent and Similar Triangles Method (and their restart-strongly convex variants) lead (up to a logarithmic factor) to unimprovable estimations, collected in the table below (we assume that all parameters M, L, R, μ we choose correspond to the norm $\|\cdot\|$ – this isn't true for A. Nemirovski example):

N	$ F(y) - F(x) \leq M \ y - x\ $	$\ \nabla F(y) - \nabla F(x)\ _* \leq L \ y - x\ $
$F(x)$ convex	$\frac{M^2 R^2}{\varepsilon^2}$	$\sqrt{\frac{LR^2}{\varepsilon}}$
$F(x)$ μ -strongly convex	$\frac{M^2}{\mu\varepsilon}$	$\sqrt{\frac{L}{\mu}} \left\lceil \ln \left(\frac{\mu R^2}{\varepsilon} \right) \right\rceil$

If norm is non euclidian then the last row is true up to $O(\ln n)$ -factor.

How to choose norm and prox function?

Arkadi Nemirovski, 1979

$$a = \frac{2 \log n}{2 \log n - 1} \approx 1 + \frac{1}{2 \log n}$$

$Q = B_p^n(1)$	$1 \leq p \leq a$	$a \leq p \leq 2$	$2 \leq p \leq \infty$
$\ \cdot \ $	$\ \cdot \ _a$	$\ \cdot \ _p$	$\ \cdot \ _2$
$d(x)$	$d(x) = \frac{1}{2(a-1)} \ x\ _a^2$	$d(x) = \frac{1}{2(p-1)} \ x\ _p^2$	$\frac{1}{2} \ x\ _2^2$
R^2	$O(\log n)$	$O((p-1)^{-1})$	$O(1)$

Structural optimization (looking into the Black Box)

Composite optimization (Yu. Nesterov, 2007) $f(x) + h(x) \rightarrow \min_{x \in Q}$

$$\text{Mirr}_{x^k}(\alpha \partial f(x^k)) := \arg \min_{x \in Q} \left\{ \langle \alpha \partial f(x^k), x - x^k \rangle + \alpha h(x) + V(x, x^k) \right\},$$

$$\varphi_{k+1}(x) := \varphi_k(x) + \alpha_{k+1} \left[f(y^{k+1}) + \langle \nabla f(y^{k+1}), x - y^{k+1} \rangle + h(x) \right].$$

Rates of convergences of MD and STM don't change and determine only by properties of function $f(x)$ as it was previously (without $h(x)$).

Example (L1 optimization). $h(x) = \lambda \|x\|_1$, $d(x) = \|x\|_2^2 / 2$, $Q = \mathbb{R}^n$,

$$\left\{ \left(\left| x_i^k - \frac{1}{L} \nabla_i f(x^k) \right| - \frac{\lambda}{L} \right)_+ \text{sign} \left(x_i^k - \frac{1}{L} \nabla_i f(x^k) \right) \right\}_{i=1}^n =$$

$$= \arg \min_{x \in \mathbb{R}^n} \left\{ \langle \nabla f(x^k), x - x^k \rangle + \lambda \|x\|_1 + (L/2) \|x - x^k\|_2^2 \right\}.$$

Structural optimization (looking into the Black Box)

MinMax problem (idea A. Nemirovski, 1979; Yu. Nesterov, 2004)

$$F(x) = \max_{l=1,\dots,m} f_l(x) + h(x) \rightarrow \min_{x \in Q}$$

$$u^{k+1} = \arg \min_{u \in Q} \left\{ \alpha_{k+1} \left\{ \max_{l=1,\dots,m} \left[f_l(y^{k+1}) + \langle \nabla f_l(y^{k+1}), u - y^{k+1} \rangle \right] + h(u) \right\} + V(u, u^k) \right\}.$$

Unfortunately in general this sub-problem isn't simple enough. But the number of such iteration of Turins' variant of STM will be the same (up to a constant) as in the case of previous slide

$$F(x^N) - F_* \leq \frac{8LR^2}{(N+1)^2}, \quad \|\nabla f_l(y) - \nabla f_l(x)\|_* \leq L\|y - x\|, \quad x, y \in Q, \quad l = 1, \dots, m.$$

One can also generalize this result further:

Lan G. Bundle-level methods uniformly optimal for smooth and non-smooth convex optimization // Math. program. Ser. A. 2015. V. 149. no. 1. P. 1–45.

Note that $F(x)$ isn't necessarily smooth even with $h(x) \equiv 0$. So if we can calculate at each iteration only $\partial F(x^k)$ then one can think that such a methods (that used only this information) can't converges faster then $O(MR/\sqrt{N})$ according to lower bound from the table above. But there is no contradiction with the previous slide since there we have more information $\{\nabla f_l(x^k)\}_{l=1}^m$ and we allow ourselves to solve at each iteration non trivial problem (in general). Nevertheless, estimation $O(MR/\sqrt{N})$ is not the right lower bound, for example, when $f_l(x) = \langle c_l, x \rangle$, because the problem has a special structure (functional has a simple Fenchel's type representation). This structure allows to replace the problem by (Nesterov's smoothing, 2005)

$$F_\gamma(x) = \gamma \ln \left(\sum_{l=1}^m \exp(\langle c_l, x \rangle / \gamma) \right) \rightarrow \min_{x \in Q}, \quad \gamma = \varepsilon / 2 \ln m.$$

If one can find such x^N that

$$F_\gamma(x^N) - F_\gamma^* \leq \varepsilon/2$$

then for the same x^N one will have

$$F(x^N) - F_* \leq \varepsilon.$$

The above is obvious from the dual regularized representation

$$F(x) = \max_{y \in \mathcal{S}_m(1)} \sum_{l=1}^m y_l \langle c_l, x \rangle; \quad F_\gamma(x) = \max_{y \in \mathcal{S}_m(1)} \left\{ \sum_{l=1}^m y_l \langle c_l, x \rangle - \gamma \sum_{l=1}^n y_l \ln y_l \right\}.$$

Since $\sum_{l=1}^n y_l \ln y_l$ is 1-strongly convex in 1-norm then

$$\|\nabla F_\gamma(y) - \nabla F_\gamma(x)\|_2 \leq L_{F_\gamma} \|y - x\|_2, \quad L_{F_\gamma} = \frac{1}{\gamma} \max_{l=1, \dots, m} \|c_l\|_2^2.$$

So we have $N = O\left(\max_{l=1, \dots, m} \|c_l\|_2 R_2 \sqrt{\ln m} / \varepsilon\right)$ instead of $N = O\left(\max_{l=1, \dots, m} \|c_l\|_2^2 R_2^2 / \varepsilon^2\right)$.

Conditional problems

In **smooth case** the main trick is to reduce

$$f_0(x) \rightarrow \min_{f_l(x) \leq 0, l=1, \dots, m; x \in Q}$$

to the searching of

$$F(t) = \min_{x \in Q} \max \{f_0(x) - t, f_1(x), \dots, f_m(x)\}.$$

The last problem (with fixed t is considered above).

Our task is to find the minimal t_* such that $F(t_*) = 0$. Since $F'(t) = \{0, -1\}$ one can do it with precision ε using $\sim \log(\varepsilon^{-1})$ recalculations of $F(t)$.

Nesterov Yu. Introduction Lectures on Convex Optimization. A Basic Course. Applied Optimization. – Springer, 2004.

In non smooth case

$$f(x) \rightarrow \min_{g(x) \leq 0; x \in Q},$$

where $\|\partial f(x)\|_* \leq M_f$, $\|\partial g(x)\|_* \leq M_g$. Let's $h_g = \varepsilon_g / M_g^2$, $h_f = \varepsilon_g / (M_f M_g)$,

$$\begin{cases} x^{k+1} = \text{Mirr}_{x^k} (h_f \partial f(x^k)), & \text{if } g(x^k) \leq \varepsilon_g, \\ x^{k+1} = \text{Mirr}_{x^k} (h_g \partial g(x^k)), & \text{if } g(x^k) > \varepsilon_g, \end{cases} \quad k = 1, \dots, N,$$

and the set I of such indexes k , that $g(x^k) \leq \varepsilon_g$. Then for $N \simeq 2M_g^2 R^2 / \varepsilon_g^2$

$$f(\bar{x}^N) - f_* \leq \varepsilon_f = M_f \varepsilon_g / M_g, \quad g(\bar{x}^N) \leq \varepsilon_g,$$

where $\bar{x}^N = \frac{1}{N_I} \sum_{k \in I} x^k$, $N_I = |I|$, $N_I \geq 1$.

High-order methods

In 1989 Nemirovski–Nesterov propose a general (Newton’s type) method to solve large class of convex optimization problems of these type

$$\langle c, x \rangle \rightarrow \min_{x \in Q}, \quad // \quad \text{Note: } F(x) \rightarrow \min_{x \in Q} \sim y \rightarrow \min_{x \in Q, F(x) \leq y}$$

Where convex (but rather complex for projections) set Q imposed by ν -self-concordant barrier function $F_Q(x)$. As we have already known many interesting convex problems have such representation with $Q = \mathbb{R}_+^n$, $Q = S_+^n$ (up to affine transformation). For this sets

$$F_Q(x) = -\sum_{i=1}^n x_i \ln x_i \quad \text{and} \quad F_Q(X) = -\ln \det(X)$$

are corresponding n -self-concordant barrier (and in general $\nu = O(n)$).

Interior Point Method (inserted in CVX)

The proposed method looks as follows

$$t^{k+1} = \left(1 + \frac{1}{13\sqrt{\nu}} \right) t^k,$$

$$x^{k+1} = x^k - \left[\nabla^2 F_Q(x^k) \right]^{-1} \left(t^{k+1} \cdot c + \nabla F_Q(x^k) \right).$$

With proper choose of starting point (these procedure costs $O(\sqrt{\nu} \log \nu)$) described IPM has the following rate of convergence $N = O(\sqrt{\nu} \log(\nu/\epsilon))$.

This estimation is better (since $\nu = O(n)$) than lower bound $\sim n \log(\epsilon^{-1})$ (we consider here the case $N \geq n$). There is no contradiction here, because of additional assumption about the structure of the problem.

Can one obtain something better?

The question is natural since local convergence of Newton method is $\sim \log \log(\varepsilon^{-1})$. As it was shown by A. Nemirovski (1979) this rate of convergence could be in principal be realized globally. But the price should be to high – rather complex iterations. Even in IPM realization we have in principle the following complexity of one iteration $O(n^3)$ (this can be reduced for the special cases). Moreover, it was also shown that even in \mathbb{R}^1 for the function $f(x)$, with $1 \leq f''(x) \leq 2$, $|f^{(k)}(x)| \leq 1$, $k = 1, 3, \dots, m$, $m \gg 1$ the lower bound will be $\sim c_m \log \log(\varepsilon^{-1})$ (here we can asked oracle as much derivatives $k \leq m$ as we want).

IPM is a powerful tool that finds applications to real large scale convex problems ($n \leq 10^4$). Especially for Semi Definite Programming (see CVX).

Semi Definite Relaxation (MAX CUT)

$$f(x) = \frac{1}{2} \sum_{i,j=1,1}^{n,n} A_{ij} (x_i - x_j)^2 \rightarrow \max_{x \in \{-1,1\}^n},$$

where $A = \left\| A_{ij} \right\|_{i,j=1,1}^{n,n}$ ($A = A^T$).

Let's introduce

$$L = \text{diag} \left\{ \sum_{j=1}^n A_{ij} \right\}_{i=1}^n - A,$$

ζ – random vector, uniformly distributed on a Hamming cube $\{-1,1\}^n$.

Note, that

$$f(x) = \langle x, Lx \rangle.$$

Simple observation:

$$E\langle \zeta, L\zeta \rangle \geq 0.5 \max_{x \in \{-1,1\}^n} \langle x, Lx \rangle.$$

Could we do better?

$$\max_{x \in \{-1,1\}^n} \langle x, Lx \rangle = \max_{x \in \{-1,1\}^n} \langle L, xx^T \rangle \leq \max_{\substack{X \in S_+^n \\ X_{ii}=1, i=1,\dots,n}} \langle L, X \rangle // \text{SDP problem!}$$

The book of Goemans–Williamson, 1995

Let Σ be the solution of SDP problem. Let

$$\xi \in N(0, \Sigma), \zeta = \text{sign}(\xi).$$

Then (the constant is unimprovable if $P \neq NP$ – Unique Games Conjecture)

$$E\langle \zeta, L\zeta \rangle \geq 0.878 \max_{x \in \{-1,1\}^n} \langle x, Lx \rangle.$$

“Optimal” methods aren’t always optimal indeed

We can reduce Google problem to

$$f(x) = \frac{1}{2} \|Ax\|_2^2 \rightarrow \min_{x \in S_n(1)},$$

We will use not optimal (in terms the number of oracle calls) conditional gradient method (Frank–Wolfe, 1956). But we assume that the number of nonzero elements at each row and each column smaller then $s \ll \sqrt{n}$.

We choose starting point at one of the simplex vertex x^1 . Induction step

$$\langle \nabla f(x^k), y \rangle \rightarrow \min_{y \in S_n(1)} .$$

Let’s denote the solution of this problem by

$$y^k = (0, \dots, 0, 1, 0, \dots, 0),$$

where 1 is posed at the position

$$i_k = \arg \min_{i=1, \dots, n} \partial f(x_k) / \partial x^i.$$

The main algorithm looks as follows

$$x^{k+1} = (1 - \gamma_k) x^k + \gamma_k y^k, \quad \gamma_k = \frac{2}{k+1}, \quad k = 1, 2, \dots,$$

One can obtain that (here we also used that $f_* = 0$)

$$f(x^N) - f_* \leq \frac{2L_p R_p^2}{N+1}, \quad // \text{ for optimal method } O\left(\frac{LR^2}{N^2}\right)$$

$$R_p^2 = \max_{x, y \in S_n(1)} \|y - x\|_p^2, \quad L_p = \max_{\|h\|_p \leq 1} \langle h, A^T A h \rangle = \max_{\|h\|_p \leq 1} \|Ah\|_2^2, \quad 1 \leq p \leq \infty.$$

Since we work on a simplex we choose $p = 1$. As a result

$$R_1^2 = 4, \quad L_1 = \max_{i=1, \dots, n} \|A^{(i)}\|_2^2 \leq 2.$$

Hence for $f(x^N) \leq \varepsilon^2/2$ ($\|Ax^N\|_2 \leq \varepsilon$) we have to do $N = 32\varepsilon^{-2}$ iterations ($N \leq n \Rightarrow \varepsilon \geq n^{-1/2}$, but since $\|(n^{-1}, \dots, n^{-1})\|_2 = n^{-1/2}$, here we are interested in $n^{-1} \ll \varepsilon \ll n^{-1/2}$). One can show that after $O(n)$ preprocessing each iteration will cost $O(s^2 \ln(n/s^2))$. So the total complexity will be

$$O\left(n + s^2 \ln(n/s^2) / \varepsilon^2\right),$$

instead of total complexity of “optimal” method STM $O(sn/\varepsilon)$.

Спасибо за внимание.
